

~~Python~~ Python basics:-

- high-level language → logical similar to human logic.
- dynamically typed → data type is ^{not} explicitly defined
- multiparadigm → need not stick one kind of logic.
- procedural → line by line.
object oriented as well.
- built applications.
- vast library ~~and~~ support.
- simplicity of language.

Kernels → different environments by python.

↓
can be associated with various versions of python

(1)
conda environment

notebook → jupyter.

in jupyter

↓
no need of explicit print statement

Data types of python: (variable) ^{→ reference object.}

int, float,

→ type casting

↓
to change the data type
of pre declared data type.

→ implicit, → explicit
↓
converts internally
based on operations
str(a) manually

→ float, boolean.

→ Strings (*)

single (a) a double quote

→ naming → should not start number / special characters
→ no inbuilt functions.

→ complex data type

→ no need of declaration, we can directly assign a variable.

→ dynamic typing → reference shift if datatype change.

→

Operators in python

→ +, -, *, /, %, **, //

↓ ↓ ↓
~~divided~~ mod floor quotient
quotient

→ comparators: (==, & ==)

==, !=, <, >, <=, >=

→ logical

and, or, not

→ assignment operators

x += x *=

x -=

→ input function. (dynamic assignment).

name = ^{int}input("Enter your name: ")

→ f strings

.format

→ f" I am {age} years old, born in {year}"

→ print(" I love {}, my subject is {}".format(language, subject).

→ if, ~~else~~, elif
